Magic's Decision Desk

Project showcase

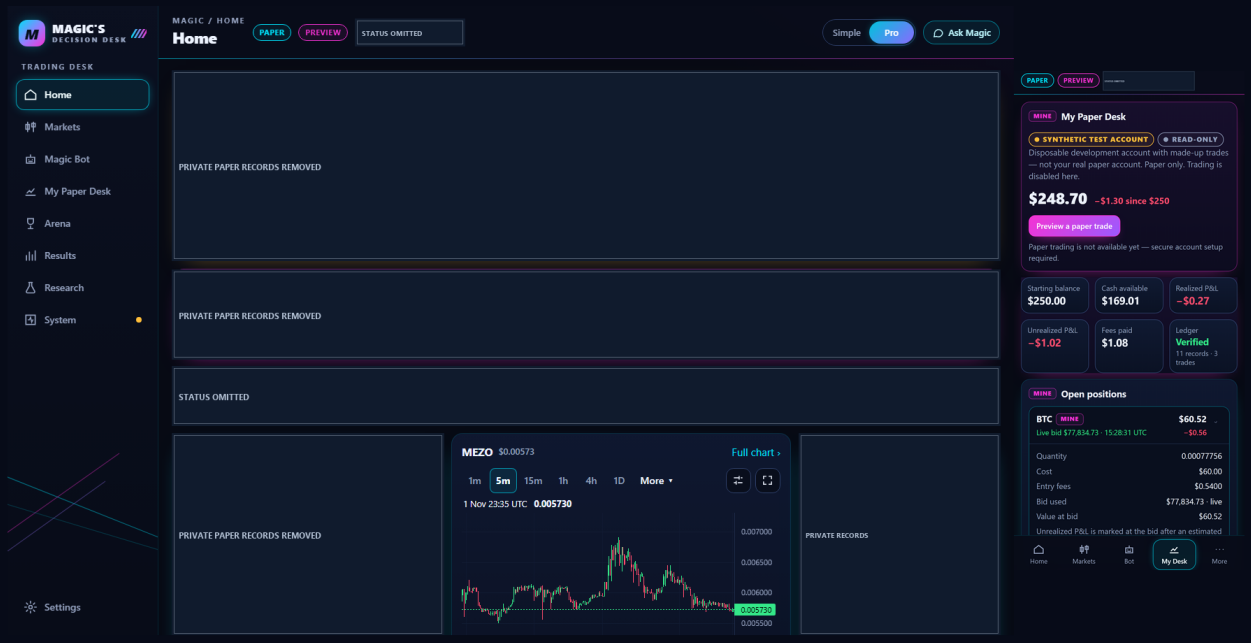

From market noise to an accountable decision

A paper-only system built around evidence, separation and replay

Evidence edition • 2 November 2026

Paper-only development interface. M6 read view is separate from planned M7 authentication and M8 writes.

The idea behind the interface

Magic's Decision Desk explores a complete decision process: acquire public market data, filter and rank opportunities, evaluate entry rules, simulate execution, preserve an auditable record and review the result. It is for an owner investigating systematic decisions without authorizing real-money orders.

Its $250 starting-account concept makes comparisons concrete. The automated bot, personal My Paper Desk and blind Arena contest remain separate accounting contexts. Public Coinbase quotes can be live while strategy decisions are old and the bot is stopped.

The engineering underneath

Arrow order simplifies the data path. Control and safety authority remain separate from read-only presentation.

• Read PAPER/PREVIEW, bot heartbeat status, last cycle and quote time. A live price does not mean the bot is running. Start by reading state

• Top 5 ranks candidates; Qualified Top 2 narrows them. Selection is not a buy recommendation and readiness needs a valid observation window. Compare the opportunity lists

• Choose a pair, interval, range and scale. Read source, timestamp, gaps and unavailable-series reasons before interpreting a plot. Inspect the chart

Failures that improved the design

Readiness is more than a green chart

The entry window requires at least 12 distinct observations across 600 seconds. Out-of-order times, excessive gaps, policy changes and stale observations reset or block readiness. A ten-minute label alone is not enough.

Some derived candles cannot be trusted

Recorded reconciliation found thin-coin native intervals inconsistent with aggregates. The implementation withholds unverified derived series rather than drawing an apparently precise but unsupported chart.

An intent is not a fill

M6 journals intent then fill or refusal under transaction control. Repeated client IDs return the same outcome; conflicting content is refused. Interrupted intents close as refused rather than becoming retroactive trades.

M7 sign-in and the later M8 boundary

M7 is design and research only. The proposal combines private networking with per-device WebAuthn passkeys, short opaque sessions, server-side owner checks, CSRF/origin checks, step-up verification and revocation. None is presented as an enabled sign-in experience.

The design was motivated in part by the limits of proxy identity: local software can forge those headers, and the backend cannot infer the original device merely from a loopback request. The proposed application session is the real write gate.

M8 comes later: authenticated personal-paper writes against a synthetic desk first, followed by separately authorized owner desk creation. Live source wiring, transaction acceptance, device tests and rollback must precede an operational Confirm button. Real-money orders remain outside this paper-only project.

- M7a through M7e cover store, passkey verification, sessions, screens and real-device acceptance.
- Dependency, enrollment and step-up choices still need owner decisions.
- The existing ticket continues to be a preview until the write boundary is implemented and verified.

Built with AI directed by a builder

Daniel directed the product objectives, reviewed the visual direction and refined the work through feedback. The repositories preserve AI-assisted implementation, tests, checkpoints and explicit gates. This portfolio credits product direction and technical investigation without claiming Daniel personally hand-coded every component.

Recorded owner iPhone review drove typography, density and chart corrections. The engineering emphasis is the whole decision-to-record chain, not an unsupported trading-performance claim.

• From market noise to an accountable decision.

• Current status: paper-only development dashboard and synthetic M6 read view; M7/M8 planned.

• Detailed technical documentation is retained privately. This portfolio presents a reviewed summary.
