Formula None Fitness

Project showcase

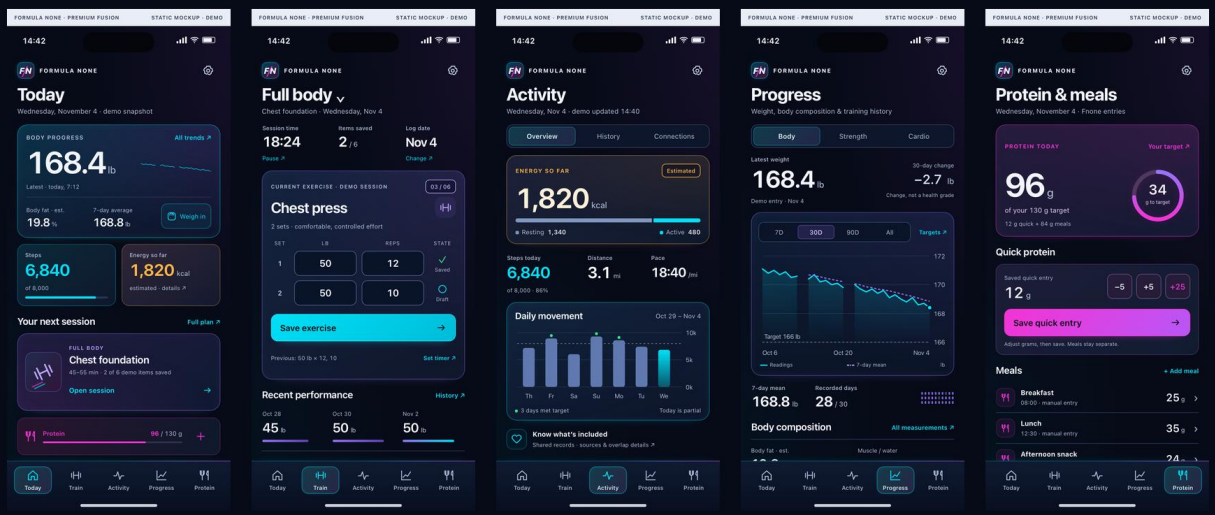

Personal fitness software at the hardware boundary

Native iOS records, a reverse-engineered scale and an honest watch experiment

Evidence edition • 2 November 2026

Premium Fusion is static design artwork with fictional data. Native iOS and hardware paths have separate status.

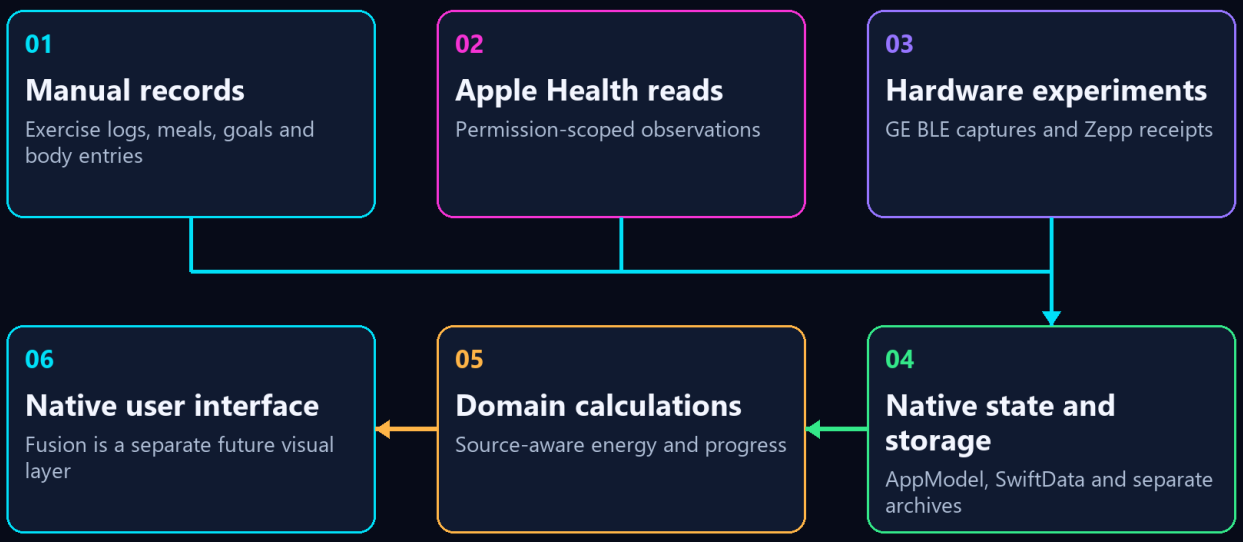

The idea behind the interface

Formula None brings workout logging, activity, body measurements, personal goals and nutrition into a native iOS project. Its engineering work extends beyond screen design into consumer-scale communication, source-aware energy calculations and a watch-to-phone reporting experiment.

Premium Fusion supplies the approved visual direction. Today M1 is now implemented in the iOS Simulator with isolated fictional data. The other six Fusion areas remain artwork. Physical-device HealthKit, scale and watch acceptance remain separate.

The engineering underneath

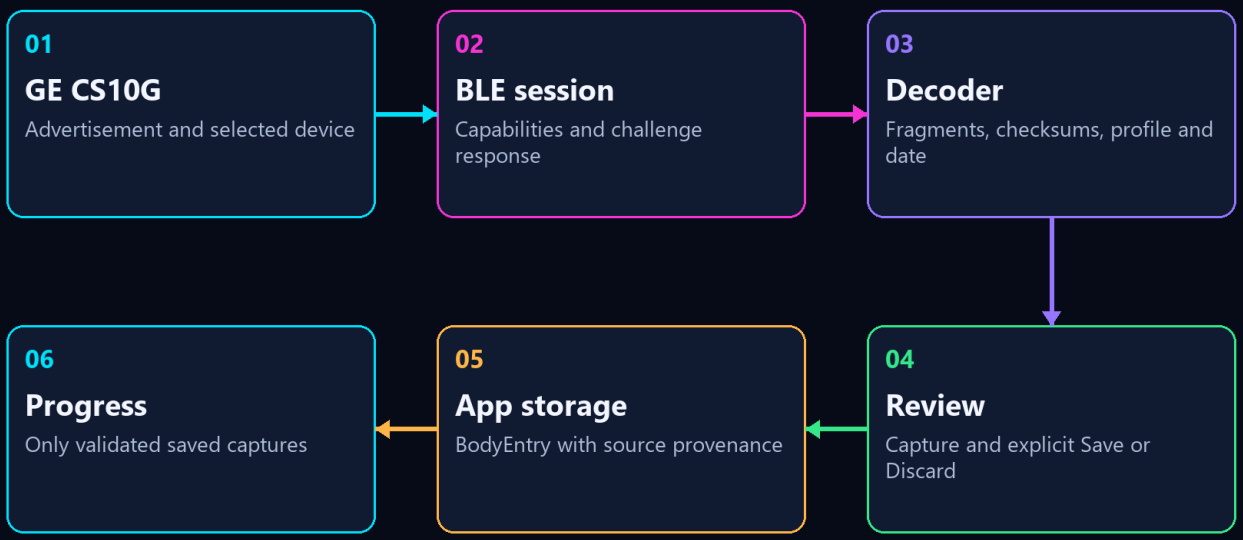

Three distinct input paths meet the native application. Experimental hardware does not write Apple Health records.

• Use the current native tabs: Today, Plan, Activity, Protein and More. Fusion proposes Train and a direct Progress tab instead. Open the actual app

• Plan permits a different workout/date, records two strength sets or cardio fields, and separates drafts from saved logs. Choose a date and workout

• Session and set timing support the log. Save the exercise deliberately; missing timing is not a performance score. Use timers as context

A scale protocol built into the app

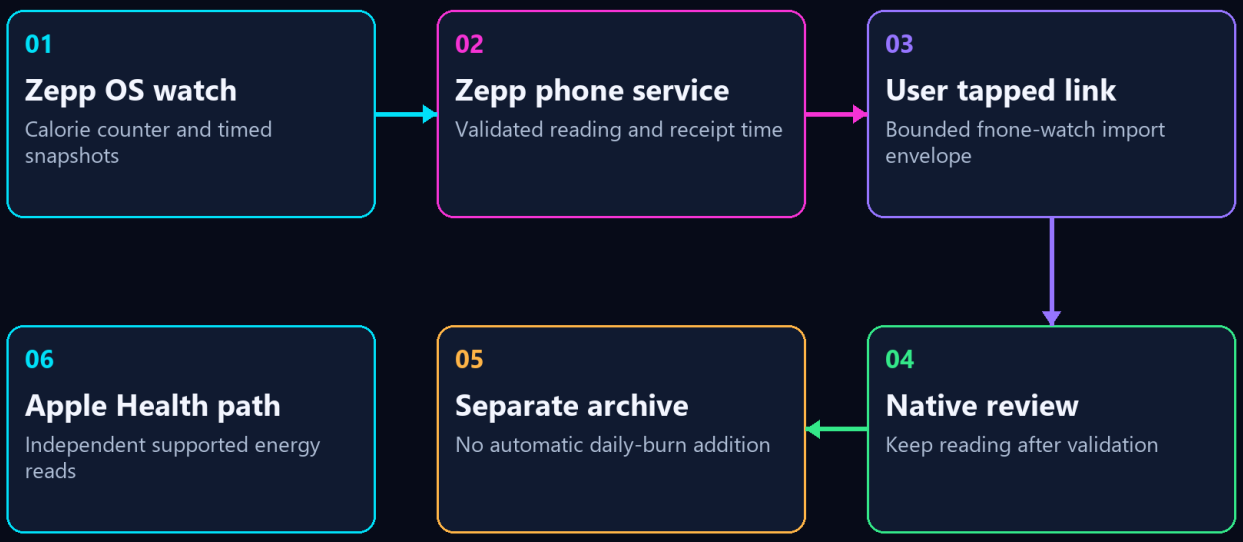

Experimental device integration. App-local saves are separate from HealthKit reads. No live scale trial was run.

GE CS10G integration includes BLE identity, challenge-response authentication, packet sequencing, measurement interpretation, profile isolation and reviewed local save. It is substantial source-backed engineering, with physical-device acceptance still experimental.

The native app keeps unavailable composition values unknown and prevents unverified captures entering progress. The direct path is separate from Apple Health reads.

Watch reporting with honest freshness

The available companion targets Zepp OS, not watchOS. The link failure and hardware-validation gap remain explicit.

The inspected companion targets Zepp OS Active 2, not watchOS. It collects daily counters with source timing, stores phone receipts and supports reviewed native import. A failed phone link prompted a metadata-only BLE alternative.

Automatic reporting, background reliability and counter meaning remain unverified. Apple Watch data can separately enter through iPhone HealthKit reads; no completed native Apple Watch app is claimed.

Built with AI directed by a builder

Daniel directed the product objectives, reviewed the visual direction and refined the work through feedback. The repositories preserve AI-assisted implementation, tests, checkpoints and explicit gates. This portfolio credits product direction and technical investigation without claiming Daniel personally hand-coded every component.

The source preserves a native application, approved design artwork and consumer-hardware experiments. Today M1 has three recorded focused UI passes in Simulator. One existing regression assertion still fails on the unchanged baseline; no complete test-suite or hardware pass is claimed.

• Personal fitness software at the hardware boundary.

• Current status: Today M1 runs in Simulator with fictional data; the other Fusion screens remain artwork. Hardware paths are experimental.

• Detailed technical documentation is retained privately. This portfolio presents a reviewed summary.
